CERTIFICATE

This is to certify that the Project Work entitled "**RYTHUMITRA- A MULTILINGUAL VOICE-FIRST AI FARMING COMPANION**" is a bonafide work carried out by **Pranavi Chamakura (22WH1A1262)**, **Neha Patnamshetty (22WH1A1263)**, **Priyanka Sandhila (22WH1A1264)**, and **Siri Sanjana Kambam (22WH1A1265)** in partial fulfillment for the award of B.Tech. degree in **Information Technology**, **BVRIT Hyderabad College of Engineering for Women**, Bachupally, Hyderabad, affiliated to Jawaharlal Nehru Technological University Hyderabad, under my guidance and supervision. The results embodied in this project work have not been submitted to any other University or Institute for the award of any degree or diploma.

Internal Guide	**Head of the Department**
Mr. Ch. Anil Kumar	Dr. P Kayal
Assistant Professor	Professor & HoD
Department of IT	Department of IT

External Examiner

DECLARATION

We here by declare that the work presented in this project entitled **"RYTHUMITRA- A MULTILINGUAL VOICE-FIRST AI FARMING COMPANION"** submitted towards completion of Major Project Work in IV year of B.Tech., IT at 'BVRIT HYDERABAD College of Engineering for Women', Hyderabad is an authentic record of our original work carried out under the guidance of **Dr. P Kayal**, Professor & HOD, Department of IT.

Ms. Pranavi Chamakura
(22WH1A1262)

Ms. Neha Patnamshetty
(22WH1A1263)

Ms. Priyanka Sandhila
(22WH1A1264)

Ms. Siri Sanjana Kambam
(22WH1A1265)

ACKNOWLEDGEMENT

We would like to express our sincere thanks to **Dr. K V N Sunitha, Principal, BVRIT Hyderabad College of Engineering for Women**, for providing the working facilities in the college.

Our sincere thanks and gratitude to our HOD **Dr. P Kayal, Professor, Department of IT, BVRIT Hyderabad College of Engineering for Women** for all the timely support and valuable suggestions during the period of our project.

We are extremely thankful and indebted to our internal guide, **Mr. Ch. Anil Kumar, Assistant Professor, Department of IT, BVRIT Hyderabad College of Engineering for Women** for his constant guidance, encouragement, and moral support throughout the project.

Finally, we would also like to thank our project coordinators **Dr. P Bharathi** and **Ms. T. Sukanya**, all the faculty and staff of the IT Department who helped us directly or indirectly, and our parents and friends for their cooperation in completing the project work.

Ms. Pranavi Chamakura
(22WH1A1262)

Ms. Neha Patnamshetty
(22WH1A1263)

Ms. Priyanka Sandhila
(22WH1A1264)

Ms. Siri Sanjana Kambam
(22WH1A1265)

ABSTRACT

Agriculture plays a crucial role in the economy, yet farmers face challenges such as delayed crop disease detection, lack of real-time information, and difficulty in accessing government schemes. Existing digital solutions are often fragmented and not user-friendly for all farmers. To address these issues, this project proposes RythuMitra – A Multilingual Voice-First AI Farming Companion, an integrated platform that combines Artificial Intelligence and Blockchain technologies.

The system uses Convolutional Neural Networks (CNNs) to detect crop diseases from leaf images and provides personalized recommendations for fertilizers and pest control. It also includes a blockchain-enabled "Easy Apply" feature for secure and transparent government scheme applications, using smart contracts and IPFS for decentralized storage. Additionally, the platform offers real-time market price updates, weather-based advisories, and a voice-driven interface, including a farm diary and voice-based interaction, to improve accessibility.

The proposed system is implemented using a web-based architecture with modern technologies such as TensorFlow, Node.js, and Ethereum. The platform enhances decision-making, improves transparency, and provides a unified digital solution for farmers, contributing to smart and sustainable agriculture.

Keywords: *Smart Agriculture*, *Crop Disease Detection*, *Convolutional Neural Networks (CNN)*, *Blockchain Technology*, *IPFS (InterPlanetary File System)*, *Government Scheme Automation*, *Precision Farming*, *Multilingual Voice Interface*, *Farmer Support Systems*, *Web-Based Application*.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Agriculture plays a vital role in the economic development of many countries, particularly in developing nations like India, where a significant portion of the population depends on farming for their livelihood. Despite its importance, the agricultural sector faces numerous challenges, including crop diseases, unpredictable weather conditions, fluctuating market prices, and limited access to government support schemes. These issues directly affect crop yield, farmer income, and overall agricultural productivity.

One of the major challenges faced by farmers is the early detection of crop diseases. In many rural areas, farmers rely on traditional knowledge or delayed expert consultation, which often leads to late diagnosis and significant crop loss. Additionally, farmers struggle to access reliable and timely agricultural information, such as weather forecasts, irrigation guidance, and market price updates. This lack of real-time support results in inefficient decision-making and reduced profitability.

Another critical issue is the complexity of government schemes. Although various agricultural welfare programs are introduced by governments, many farmers are unable to benefit from them due to complicated application processes, lack of awareness, and absence of transparency. Manual verification systems further slow down the process and increase the chances of errors and fraud.

In recent years, advancements in technologies such as Artificial Intelligence (AI), Machine Learning (ML), and Blockchain have opened new opportunities to address these challenges. AI-based techniques, particularly Convolutional Neural Networks (CNNs), have shown high accuracy in detecting plant diseases from leaf images. Similarly, blockchain technology enables secure, transparent, and tamper-proof data management, making it suitable for handling sensitive applications such as government

scheme processing.

However, most existing agricultural solutions are fragmented, focusing only on a single functionality such as disease detection, weather updates, or market information. This forces farmers to use multiple applications, which reduces usability and limits the effectiveness of digital solutions.

To overcome these limitations, this project proposes “RythuMitra – A Multilingual Voice-First AI Farming Companion”, an integrated digital platform designed to support farmers through a unified ecosystem. The system combines AI-based crop disease detection, blockchain-enabled government scheme application, real-time market and weather updates, and a voice-driven farm diary into a single accessible platform. By enabling farmers to interact through voice in their preferred language, the system improves accessibility and usability, especially for users with limited literacy.

The proposed system leverages a web-based architecture, where farmers can upload crop images for disease detection, receive personalized recommendations for fertilizers and pest control, access real-time agricultural advisories, and securely apply for government schemes using blockchain and IPFS technologies. This integrated approach enhances decision-making, ensures transparency, and empowers farmers with modern digital tools.

The overall objective is to improve agricultural productivity, enhance farmer accessibility to digital tools, and support informed decision-making through an integrated smart farming platform.

1.2 Problem Definition

Farmers face multiple challenges in managing agricultural activities efficiently due to the lack of integrated and accessible digital solutions. Crop diseases are often identified at later stages, leading to severe crop damage and financial loss. Existing disease detection systems may not perform effectively in real-world conditions due to variations in lighting, background, and environmental factors.

Additionally, farmers have limited access to reliable and real-time information related to weather conditions, irrigation practices, and market prices. This lack of timely information leads to poor decision-making and reduced productivity.

Another significant issue is the difficulty in applying for government schemes. The process is often complex, time-consuming, and lacks transparency, discouraging farmers from utilizing available benefits.

Furthermore, most existing agricultural applications are text-based and support limited languages, making them difficult to use for farmers with low literacy levels. Therefore, there is a need for a unified, user-friendly, and intelligent system that can provide real-time support, accurate disease detection, multilingual interaction, and secure access to government services.

1.3 Objectives

The primary objective of this project is to develop an intelligent and integrated digital platform that assists farmers in managing agricultural activities more efficiently using advanced technologies such as Artificial Intelligence and Blockchain. The system aims to address key challenges faced by farmers and improve overall productivity and decision-making.

The specific objectives of the proposed system are as follows:

- To design and implement an AI-based crop disease detection system using Convolutional Neural Networks (CNNs) that can accurately identify diseases from leaf images under real-world conditions.
- To provide personalized and actionable recommendations for farmers, including suitable fertilizers, pesticides, irrigation practices, and preventive measures based on the detected disease.
- To develop a blockchain-enabled “Easy Apply” system that simplifies the process of applying for government schemes, ensuring transparency, security, and tamper-proof record management through smart contracts.
- To utilize IPFS (InterPlanetary File System) for secure and decentralized storage of farmer documents, reducing dependency on centralized systems and enhancing data integrity.
- To integrate real-time agricultural advisory services such as market price updates and weather forecasts, enabling farmers to make timely and informed decisions regarding crop management and sales.
- To implement a multilingual voice-based interface that allows farmers to interact with the system using speech in their preferred language, improving accessibility for users with limited literacy or technical knowledge.
- To design a user-friendly web-based platform that brings together multiple agricultural services into a single unified system, reducing the need for multiple applications.

- To ensure scalability and flexibility of the system so that it can be extended in the future to support additional crops, languages, and advanced AI models.

The overall objective is to bridge the gap between complex clinical data and patient comprehension, thereby improving healthcare accessibility, enhancing health literacy, and supporting informed decision-making.

1.4 System Modules

The proposed system consists of several key modules that work together to provide a comprehensive farming support platform:.

Crop Disease Detection Module: This module uses Convolutional Neural Networks (CNNs) to analyze images of crop leaves uploaded by farmers. It identifies diseases and provides appropriate recommendations for fertilizers, pesticides, and treatment methods.

Recommendation System: Based on the detected disease, this module suggests suitable agricultural practices, including irrigation guidance, pest control measures, and fertilizer usage to improve crop health and yield.

Blockchain-Based Scheme Module: This module enables farmers to apply for government schemes using a simplified "Easy Apply" feature. It uses blockchain technology and smart contracts to ensure transparency and security. Documents are stored using IPFS for decentralized and tamper-proof storage.

Market and Weather Advisory Module: This module provides real-time updates on market prices and weather conditions. It helps farmers make informed decisions regarding selling crops and planning agricultural activities.

Voice-Based Farm Diary Module: This module allows farmers to record daily agricultural activities using voice input in their preferred language. It improves accessibility for users with limited literacy and simplifies record-keeping.

User Interface Module: The system provides a web-based dashboard that enables users to interact with all modules easily. It is designed to be simple, intuitive, and accessible across devices.

Overall, the modular design of the system enables seamless integration of all components, ensuring efficient processing, scalability, and improved user experience.

CHAPTER 2

LITERATURE SURVEY

2.1 Related Work

The rapid advancement of digital technologies has significantly transformed the agricultural sector by introducing intelligent systems for crop monitoring, disease detection, and farmer assistance. Technologies such as Artificial Intelligence (AI), Deep Learning, Blockchain, and Mobile Computing have enabled the development of smart farming solutions. This section reviews existing research works related to crop disease detection, blockchain-based agricultural systems, AI-driven farmer support tools, and mobile-based agricultural applications.

A. Crop Disease Detection using Deep Learning

Deep learning techniques, particularly Convolutional Neural Networks (CNNs), have shown remarkable success in image-based plant disease detection. The ICAR Research Group [1] conducted an extensive study on plant disease identification using deep learning approaches. Their work analyzed various CNN architectures such as AlexNet, VGGNet, and ResNet, demonstrating high classification accuracy on benchmark datasets like PlantVillage. The study emphasized that deep learning models can automatically extract complex spatial features from leaf images, reducing the need for manual feature engineering.

However, the study primarily focuses on controlled datasets with clean backgrounds and well-captured images. In real-world agricultural environments, images often contain noise, varying lighting conditions, and background clutter, which can significantly affect model performance. Additionally, the study does not address deployment challenges such as real-time inference or integration with farmer-centric applications.

Similarly, the work by I.S.R Team [2] focuses on maize foliar disease detection using deep learning models. The study evaluates multiple CNN architectures and com-

pares their performance based on accuracy and computational efficiency. The results show that deep learning models outperform traditional machine learning techniques in disease classification tasks.

Despite achieving high accuracy, the system is limited to a single crop (maize), making it less useful for farmers cultivating multiple crops. Furthermore, the model is trained on curated datasets and does not consider real-world environmental variations, limiting its practical applicability.

The research by I.R Group [3] proposes a 2D CNN-based model for crop disease detection. The model processes leaf images through convolutional and pooling layers to extract features and classify diseases. The study reports high accuracy and demonstrates the effectiveness of CNNs in plant disease classification.

However, the model is evaluated primarily on benchmark datasets and lacks robustness in field conditions. Factors such as partial leaf damage, overlapping leaves, and inconsistent lighting can reduce the reliability of predictions. Additionally, the system does not provide actionable recommendations to farmers after disease detection.

B. Advanced Deep Learning and Computer Vision Techniques

Recent advancements in deep learning have introduced more efficient and powerful architectures for plant disease detection. The S.A.R Team [4] conducted a systematic review of deep learning models used in agriculture, including EfficientNet, Vision Transformers (ViT), and transfer learning techniques. The study highlights that these models can achieve higher accuracy while reducing computational complexity when properly optimized.

The research also emphasizes the importance of data augmentation techniques such as rotation, flipping, and scaling to improve model generalization. Domain adaptation techniques are suggested to enhance performance in real-world scenarios where data distribution differs from training datasets.

Similarly, the S.P.A Group [5] explored the application of deep learning and computer vision in precision agriculture. Their study highlights the role of lightweight models that can be deployed on mobile and edge devices for real-time inference. The research also discusses challenges such as limited availability of labeled datasets and high computational requirements.

Despite these advancements, most models require powerful hardware and large datasets, making them difficult to deploy in rural or resource-constrained environments. Additionally, these studies focus primarily on model accuracy and do not address integration with complete agricultural support systems.

C. Blockchain Technology in Agriculture

Blockchain technology has emerged as a promising solution for ensuring transparency, security, and traceability in agricultural systems. The study by Granthaalayah [6] explores the application of blockchain in agriculture, particularly in supply chain management. The research highlights how blockchain can provide immutable records, reduce fraud, and improve trust among stakeholders.

However, the study is largely conceptual and does not provide a practical implementation tailored for farmers. It focuses mainly on supply chain transparency rather than direct farmer benefits such as scheme applications or advisory services.

The work by S.C.S Authors [7] introduces blockchain-assisted federated learning for secure data sharing. This approach combines the privacy-preserving capabilities of federated learning with the security of blockchain technology. It ensures that data remains decentralized while enabling collaborative model training.

Although the approach is innovative, it is complex and computationally intensive. It may not be suitable for small-scale farmers due to resource constraints and implementation complexity.

Similarly, the research by R. Authors [8] focuses on blockchain applications in food supply chain systems. The study demonstrates improved traceability and transparency in food distribution networks.

However, the system is primarily designed for logistics and supply chain management and does not directly address farmer-centric needs such as crop monitoring or scheme application processes.

D. AI-Based Chatbots and Farmer Support Systems

AI-based chatbots have been developed to assist farmers by providing answers to agricultural queries. The study by I. Authors [9] proposes a chatbot system that uses Natural Language Processing (NLP), Speech-to-Text (STT), and Text-to-Speech (TTS) technologies to interact with farmers.

The chatbot enables users to ask questions related to crops, fertilizers, and weather conditions. This improves accessibility, especially for farmers who are not familiar with digital interfaces.

However, the system is limited to predefined responses and lacks the ability to handle complex or context-aware queries. It also supports only a single language, making it less effective in multilingual regions like India. Additionally, it does not integrate with other modules such as disease detection or scheme applications.

E. Mobile and Digital Technologies in Agriculture

Mobile technology has played a significant role in improving access to agricultural information. The study by A.R Group [10] emphasizes the importance of user-friendly mobile applications in agriculture. It highlights that simple interfaces and low-bandwidth support are essential for farmer adoption.

The research shows that mobile applications can provide useful information such as weather updates, market prices, and farming tips. However, most applications are text-based and lack advanced features such as AI-driven analysis and real-time recommendations.

Furthermore, these applications are often fragmented, requiring farmers to use multiple platforms for different services. This reduces usability and limits the effectiveness of digital solutions.

2.2 Research Gap

Despite significant advancements in agricultural technologies, several critical challenges remain unresolved, limiting their effectiveness in real-world scenarios:

1. **Lack of Integrated Platforms:** Most existing systems focus on individual functionalities such as disease detection, chatbot assistance, or market information. There is no unified platform that combines all essential agricultural services in one system.

2. **Limited Real-World Robustness:** Deep learning models are typically trained on curated datasets and may fail under real-world conditions due to environmental variations such as lighting changes, background noise, and leaf damage.

3. **Crop-Specific Limitations:** Many research works focus on specific crops, which restricts their usability across diverse agricultural environments.

4. **Absence of Multilingual Voice Interaction:** Most existing systems rely on text-based interfaces and do not support multilingual voice interaction, making them less accessible to farmers with low literacy levels.

5. **Complex and Non-Transparent Scheme Processes:** Existing solutions do not effectively simplify or secure the process of applying for government schemes, leading to low adoption by farmers.

6. **Limited Application of Blockchain for Farmer-Centric Services:** Blockchain technology is primarily used in supply chain management rather than directly

benefiting farmers through applications such as scheme processing.

7. **Lack of Real-Time Integrated Advisory Systems:** Many systems fail to provide real-time integration of weather updates, market prices, and crop recommendations in a single platform.

The proposed system, *RythuMitra*, addresses these limitations by integrating AI-based disease detection, blockchain-enabled scheme processing, multilingual voice interaction, and real-time advisory services into a unified and scalable platform designed specifically for farmers.

CHAPTER 3

SYSTEM DESIGN

3.1 Overview

The system design of the proposed RythuMitra platform focuses on developing an integrated, scalable, and user-friendly architecture that combines Artificial Intelligence, Blockchain, and Web technologies. The system is designed to assist farmers in crop disease detection, agricultural decision-making, and secure access to government schemes through a unified platform.

The architecture follows a modular approach, where each component is responsible for a specific functionality such as disease detection, advisory services, and scheme processing. This modular design ensures flexibility, scalability, and ease of maintenance.

3.2 System Architecture

The proposed system follows a multi-layer architecture consisting of the following layers:

- **Presentation Layer (Frontend)**
- **Application Layer (Backend Services)**
- **AI/ML Layer (Disease Detection Model)**
- **Blockchain Layer (Smart Contracts)**
- **Storage Layer (IPFS and Database)**

The frontend provides a user-friendly dashboard for farmers to interact with the system. The backend handles request processing and communication between modules. The AI layer processes images for disease detection, while the blockchain layer ensures

secure and transparent scheme applications. The storage layer manages user data and documents.

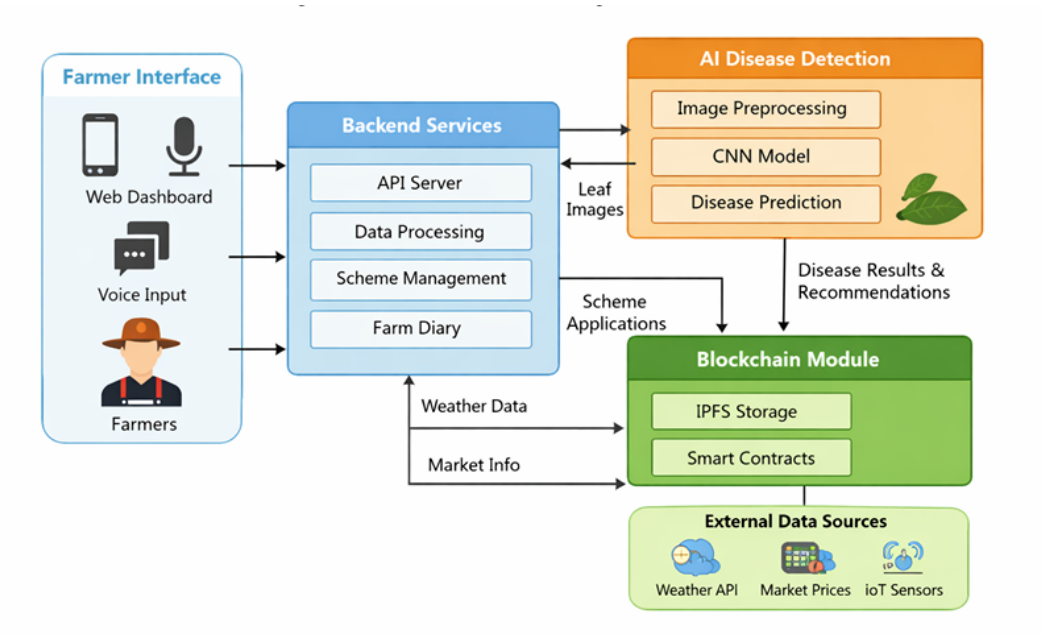

Fig. 3.1 System Architecture of RythuMitra

3.3 Design Components

3.3.1 Frontend Design

The frontend of the system is developed using HTML, CSS, and JavaScript to provide an intuitive and interactive user interface. The dashboard allows farmers to upload crop images, access market and weather information, and apply for government schemes.

The design focuses on simplicity and accessibility, ensuring that farmers with limited technical knowledge can easily navigate the platform.The interface also supports voice-based interaction, allowing users to provide input through speech and navigate the system more easily. Features such as multilingual support and clear visual elements enhance user experience.

3.3.2 Backend Design

The backend is implemented using Node.js, which handles all server-side operations. It manages user requests, processes API calls, and coordinates communication between different modules of the system.

The backend also integrates with external APIs for fetching real-time weather data and market prices. It ensures efficient data processing and smooth interaction between

the frontend and other system components.

3.3.3 AI Model Design

The AI module is responsible for crop disease detection using Convolutional Neural Networks (CNNs). The model is trained on datasets containing images of crop leaves, including rice, corn, and cotton.

The design of the AI model includes the following steps:

- Image preprocessing (resizing, normalization)
- Feature extraction using convolutional layers
- Classification using fully connected layers
- Softmax output for disease probability

The model is deployed using TensorFlow and integrated into the system through a web interface for real-time predictions.

3.3.4 Blockchain Design

The blockchain module is designed to provide secure and transparent handling of government scheme applications. Smart contracts are implemented using Solidity and deployed on the Ethereum network.

The design ensures that all transactions are recorded in a decentralized manner, preventing data tampering and improving trust in the system. Each application submitted by a farmer is stored as a transaction on the blockchain.

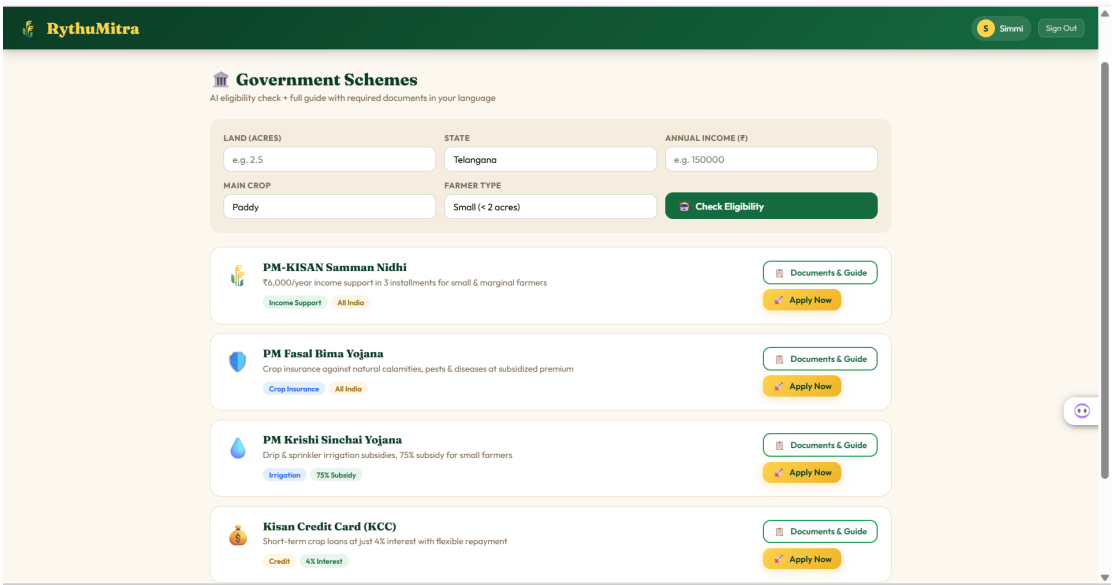

Fig. 3.2 Blockchain Design

3.3.5 IPFS Storage Design

The InterPlanetary File System (IPFS) is used for decentralized storage of farmer documents. Files such as Aadhaar, land records, and bank details are uploaded and stored securely using IPFS.

Each file is assigned a unique hash, which is stored on the blockchain. This ensures data integrity and secure access to documents without relying on centralized storage systems.

3.4 Data Flow Design

The data flow in the system describes how information moves between different modules. The key steps include:

1. Farmer uploads crop image through the frontend.
2. The image is sent to the backend for processing.
3. The AI model analyzes the image and predicts the disease.
4. The system generates recommendations based on the prediction.
5. For scheme applications, documents are uploaded to IPFS.
6. Smart contracts record the application on the blockchain.
7. User can also interact with the system using voice input, which is converted into text and processed by the backend.

This flow ensures efficient communication between all system components.

3.5 Module Design

3.5.1 Crop Disease Detection Module

This module processes uploaded images and detects crop diseases using the CNN model. It provides accurate predictions along with confidence scores.

3.5.2 Recommendation Module

Based on the detected disease, this module suggests fertilizers, pesticides, and preventive measures to improve crop health.

3.5.3 Scheme Application Module

This module allows farmers to apply for government schemes using a simplified interface. It ensures secure and transparent processing through blockchain technology.

3.5.4 Market and Weather Module

This module provides real-time updates on market prices and weather conditions, helping farmers make informed decisions.

3.5.5 Voice Interaction Module

This module enables farmers to interact with the system using voice commands. It converts speech input into text using Speech-to-Text (STT) techniques and processes user queries through the backend. The system also provides responses in a user-friendly format, improving accessibility for farmers with limited literacy.

3.6 Design Considerations

The system is designed with the following considerations:

- **Scalability:** Ability to handle a large number of users.
- **Usability:** Simple and intuitive interface for farmers.
- **Security:** Data protection using blockchain and IPFS.
- **Performance:** Efficient processing of images and requests.
- **Flexibility:** Easy integration of new features and modules.

3.7 Conclusion

The system design provides a structured and efficient framework for implementing the RythuMitra platform. By integrating AI, Blockchain, and Web technologies, the system ensures accurate disease detection, secure data handling, and improved accessibility for farmers.

CHAPTER 4

METHODOLOGY

4.1 Overview

The methodology of the proposed RythuMitra system focuses on integrating Artificial Intelligence, Blockchain, and Web technologies to provide a comprehensive farming support platform. The system follows a structured pipeline that includes data collection, preprocessing, model training, system integration, and deployment.

The methodology ensures accurate crop disease detection, secure data handling, and real-time advisory services for farmers. Each component is designed to work collaboratively to deliver an efficient and scalable solution.

4.2 Overall Workflow

The overall workflow of the system consists of multiple stages:

1. Data collection and preparation
2. Image preprocessing
3. Model training and validation
4. Disease prediction and recommendation
5. Blockchain-based scheme processing
6. Real-time advisory integration
7. Voice-based interaction processing

This structured workflow ensures smooth interaction between all system modules.

4.3 Data Collection

The dataset used for training the crop disease detection model is collected from publicly available agricultural datasets such as PlantVillage and PlantDoc. The dataset contains images of crop leaves with different disease categories and healthy conditions.

The dataset includes crops such as rice, corn, and cotton, with multiple disease classes for each crop. Each image is labeled to indicate the type of disease or healthy condition.

4.4 Data Preprocessing

Before feeding the data into the model, preprocessing steps are applied to ensure consistency and improve model performance. These steps include:

- **Image Resizing:** All images are resized to a fixed dimension suitable for model input.
- **Normalization:** Pixel values are scaled to a standard range to improve convergence.
- **Noise Removal:** Unwanted variations and distortions are minimized.
- **Data Augmentation:** Techniques such as rotation, flipping, and scaling are applied to increase dataset diversity.

These preprocessing techniques help improve the robustness of the model under real-world conditions.

4.5 Model Development

4.5.1 CNN Architecture

The crop disease detection model is built using Convolutional Neural Networks (CNNs). CNNs are effective in extracting spatial features from images and are widely used for image classification tasks.

The architecture consists of:

- Convolutional layers for feature extraction
- Pooling layers for dimensionality reduction

- Fully connected layers for classification
- Softmax layer for probability output

The model learns to identify patterns associated with different crop diseases.

4.5.2 Training and Validation

The dataset is divided into training and validation sets. The model is trained using labeled images and optimized using appropriate loss functions and optimizers.

Performance metrics such as accuracy and loss are used to evaluate the model. The trained model is validated to ensure it generalizes well to unseen data.

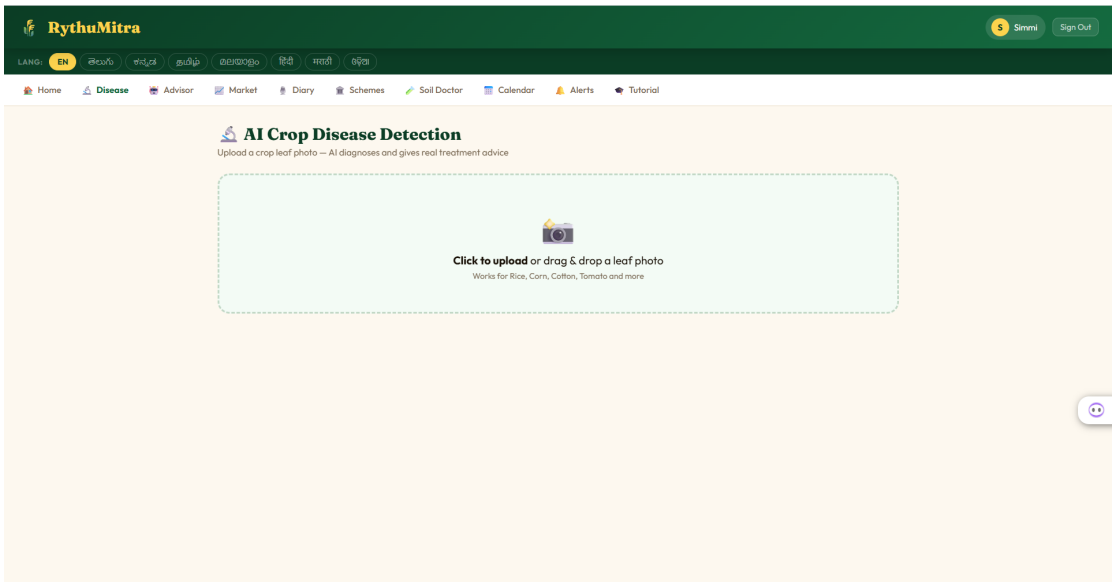

Fig. 4.1 AI Crop Disease Detection

4.6 Disease Prediction and Recommendation

Once the model is trained, it is deployed for real-time disease detection. Farmers can upload crop images through the web interface, and the system processes the images using the trained model.

Based on the predicted disease, the system generates recommendations such as:

- Suitable fertilizers
- Pest control measures
- Irrigation guidance

This helps farmers take timely corrective actions.

4.7 Voice Interaction Module

The voice interaction module enables farmers to interact with the system using speech input. This module improves accessibility, especially for users with limited literacy or technical knowledge.

The system uses Speech-to-Text (STT) techniques to convert user voice input into text. The converted text is then processed by the backend to understand the user's query and perform the required action.

Additionally, Text-to-Speech (TTS) techniques can be used to provide audio responses to users, enhancing the overall user experience.

This module ensures that farmers can interact with the platform in a more natural and user-friendly manner.

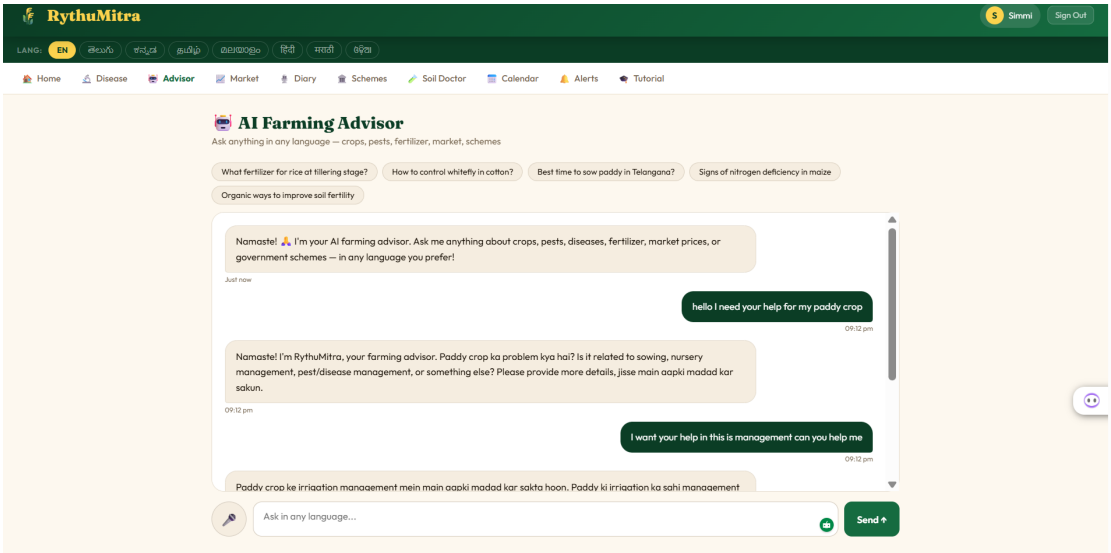

Fig. 4.2 Crop Detection

4.8 Blockchain-Based Scheme Processing

The system integrates blockchain technology to handle government scheme applications securely. The process includes:

1. Farmer uploads required documents
2. Documents are stored on IPFS
3. A unique hash is generated for each document
4. Smart contracts record application details on the blockchain

This ensures transparency, security, and tamper-proof record management.

4.9 IPFS-Based Storage

The InterPlanetary File System (IPFS) is used for decentralized storage of documents. Files are stored securely and accessed using unique hash values.

This approach eliminates dependency on centralized servers and improves data integrity.

4.10 System Integration

All modules are integrated into a unified system through a web-based architecture. The frontend interacts with the backend, which processes requests and communicates with the AI model and blockchain network.

APIs are used to fetch real-time weather and market data, ensuring seamless functionality across modules.

4.11 Deployment

The system is deployed as a web application, allowing users to access it through browsers on both desktop and mobile devices. The AI model is deployed using TensorFlow, while the backend is implemented using Node.js.

The blockchain component is deployed on the Ethereum network, and IPFS is used for decentralized storage.

4.12 Algorithm

The overall algorithm of the system is as follows:

1. Input crop image from user
2. Preprocess the image
3. Pass image to CNN model
4. Predict disease class
5. Generate recommendations
6. If scheme selected:

- Upload documents to IPFS
- Store hash on blockchain

7. If voice input is provided:
    - Convert speech to text
    - Process the query
8. Display results to user

4.13 Conclusion

The methodology provides a systematic approach to developing the RythuMitra platform. By integrating AI, Blockchain, and Web technologies, the system ensures accurate disease detection, secure data handling, and efficient farmer support services.

CHAPTER 5

IMPLEMENTATION

5.1 Overview

The implementation of the proposed RythuMitra system focuses on integrating Artificial Intelligence, Blockchain, and Web technologies into a unified platform. The system is developed as a web-based application that allows farmers to access multiple agricultural services through a single interface. Each module is implemented using appropriate technologies to ensure efficiency, scalability, and usability.

5.2 Technology Stack

The system utilizes a combination of frontend, backend, AI/ML, and blockchain technologies to achieve its functionality.

5.2.1 Frontend Technologies

The frontend of the system is developed using:

- **HTML:** Used for structuring the web pages and creating the user interface.
- **CSS:** Provides styling and layout design for better user experience.
- **JavaScript:** Enables dynamic content and user interaction within the application.

The frontend provides a dashboard where users can upload images, access information, and interact with the system easily.

5.2.2 Backend Technologies

The backend is implemented using:

- **Node.js:** Handles server-side logic and API requests.

- **Express.js:** Facilitates routing and communication between frontend and backend.

The backend processes user inputs, manages API integrations, and communicates with the AI model and blockchain network.

5.2.3 AI/ML Technologies

The crop disease detection module is developed using:

- **Python:** Used for building and training the machine learning model.
- **TensorFlow / Keras:** Used to implement the CNN model for image classification.
- **Streamlit:** Used for deploying the model interface and handling predictions.

These technologies enable efficient model training and real-time prediction.

5.2.4 Voice Interaction Technologies

- **Speech-to-Text (STT):** Used to convert user voice input into text for processing.
- **Natural Language Processing (NLP):** Used to understand and interpret the user's spoken queries.
- **Text-to-Speech (TTS):** Used to convert system responses into audio output for user interaction.
- **JavaScript / Web Speech API:** Used to implement voice recognition and interaction in the web interface.

These technologies enable seamless voice-based interaction, allowing farmers to communicate with the system using speech, thereby improving accessibility and ease of use.

5.2.5 Blockchain Technologies

The blockchain component is implemented using:

- **Solidity:** Used to write smart contracts.
- **Ethereum Network:** Used for deploying smart contracts.
- **Remix IDE:** Used for developing and testing smart contracts.

This ensures secure and transparent handling of scheme applications.

5.2.6 Web3 Integration

To connect the web application with the blockchain, the following tools are used:

- **MetaMask Wallet:** Used for user authentication and transaction signing.
- **Ethers.js:** Used for interacting with smart contracts from the frontend.

5.2.7 Storage Technologies

The system uses:

- **IPFS (InterPlanetary File System):** For decentralized storage of documents.
- **Pinata API:** For uploading and managing files on IPFS.

5.3 System Workflow

The system workflow describes how different components interact to perform various operations.

5.3.1 Crop Disease Detection Workflow

1. The user uploads a crop image through the web interface.
2. The image is sent to the backend server.
3. The backend forwards the image to the AI model.
4. The model processes the image and predicts the disease.
5. The system generates recommendations based on the prediction.
6. The results are displayed to the user.

5.3.2 Voice Interaction Workflow

1. User provides input through voice.
2. The system converts speech to text using STT.
3. The backend processes the query.
4. The response is generated and displayed.

5.3.3 Government Scheme Workflow

1. The user selects a government scheme from the dashboard.

2. Required documents are uploaded by the user.
3. Documents are stored securely in IPFS.
4. A unique hash is generated for each document.
5. Smart contracts record the application details on the blockchain.
6. The application status is displayed to the user.

5.3.4 Market and Weather Workflow

1. The system fetches real-time data from external APIs.
2. Market prices and weather conditions are processed.
3. The information is displayed on the user dashboard.

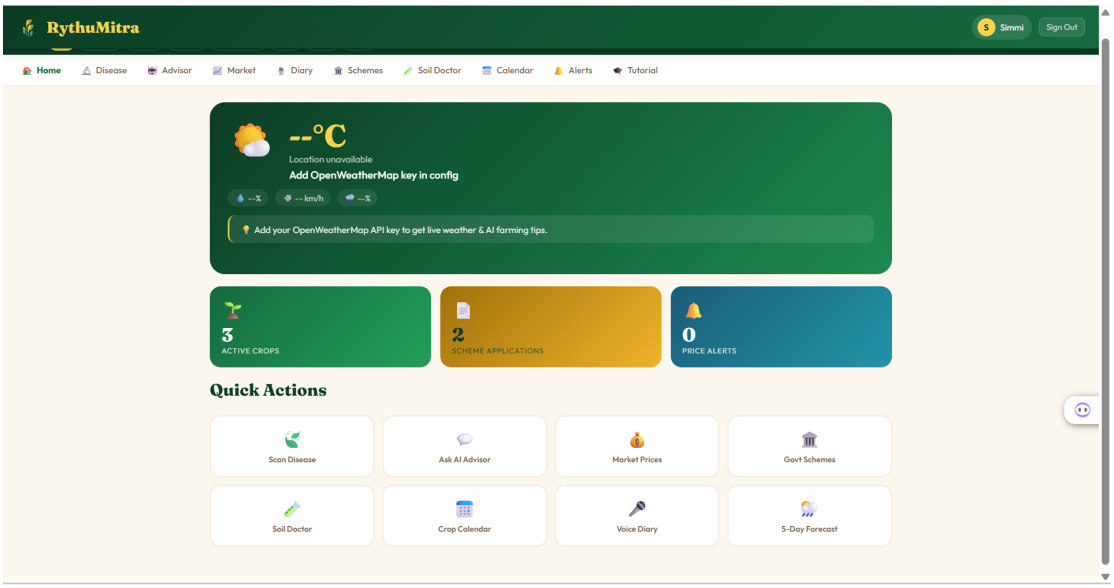

Fig. 5.1 Dashboard

5.4 Security Considerations

Security is a critical aspect of the RythuMitra system, as it handles sensitive user data and financial information.

5.4.1 Data Security

All user data and documents are securely stored using decentralized storage (IPFS), reducing the risk of data breaches associated with centralized systems.

5.4.2 Blockchain Security

Smart contracts ensure that all transactions are immutable and transparent. Once recorded, data cannot be altered, preventing fraud and unauthorized modifications.

5.4.3 User Authentication

The system uses MetaMask for secure user authentication and transaction verification. Users must approve transactions before they are recorded on the blockchain.

5.4.4 Privacy Protection

Sensitive information such as personal documents is stored securely, and access is controlled using cryptographic techniques. Only authorized users can access their data.

5.5 Deployment

The system is deployed as a web-based application to ensure accessibility across different devices.

5.5.1 Frontend Deployment

The frontend is hosted on web servers and can be accessed through browsers on desktops and mobile devices.

5.5.2 Backend Deployment

The backend server is deployed using Node.js, handling API requests and system operations.

5.5.3 AI Model Deployment

The trained CNN model is deployed using TensorFlow and integrated with the web application for real-time predictions.

5.5.4 Blockchain Deployment

Smart contracts are deployed on the Ethereum network (test network such as Sepolia). This allows secure and decentralized processing of applications.

5.5.5 IPFS Deployment

Documents are uploaded and stored on IPFS using Pinata, ensuring decentralized and tamper-proof storage.

5.6 Conclusion

The implementation of the RythuMitra system successfully integrates multiple technologies into a single platform. The use of AI enables accurate disease detection, while blockchain and IPFS ensure secure and transparent data handling. The system provides an efficient and scalable solution for modern agriculture.

CHAPTER 6

RESULTS AND DISCUSSION

6.1 Overview

This chapter presents a comprehensive analysis of the results obtained from the implementation of the proposed RythuMitra system. The system was evaluated based on its performance in crop disease detection, blockchain-based scheme processing, real-time advisory services, and overall usability. The results highlight the effectiveness of integrating Artificial Intelligence and Blockchain technologies into a unified agricultural platform.

6.2 Experimental Setup

The system was developed and tested using a web-based architecture integrating multiple technologies. The crop disease detection model was implemented using TensorFlow and trained on publicly available datasets containing labeled images of crop leaves.

The experimental setup included:

- A web-based user interface for interaction
- Backend server using Node.js and Express.js
- AI model deployed for real-time disease prediction
- Ethereum test network (Sepolia) for blockchain transactions
- IPFS (via Pinata) for decentralized document storage

Testing was performed using multiple input samples, including different crop images and simulated user interactions for scheme applications and advisory services.

6.3 Crop Disease Detection Results

The AI-based disease detection module was tested using various crop images representing different disease categories and healthy conditions. The model demonstrated effective classification capabilities and produced accurate predictions in most cases.

The system successfully identified diseases in crops such as rice, corn, and cotton. For each input image, the model generated a predicted disease label along with a confidence score, indicating the probability of the prediction.

Table 6.1 Dataset Description

Crop	Number of Classes	Classes
Rice	3	Leaf Smut, Brown Spot, Bacterial Blight
Corn	4	Blight, Common Rust, Gray Leaf Spot, Healthy
Cotton	4	Diseased Leaf, Diseased Plant, Fresh Leaf, Fresh Plant

6.3.1 Performance Evaluation

The performance of the model can be evaluated based on:

- **Accuracy:** The model achieved satisfactory accuracy on test samples.
- **Consistency:** Predictions were consistent across similar input images.
- **Generalization:** The model performed reasonably well on unseen data.

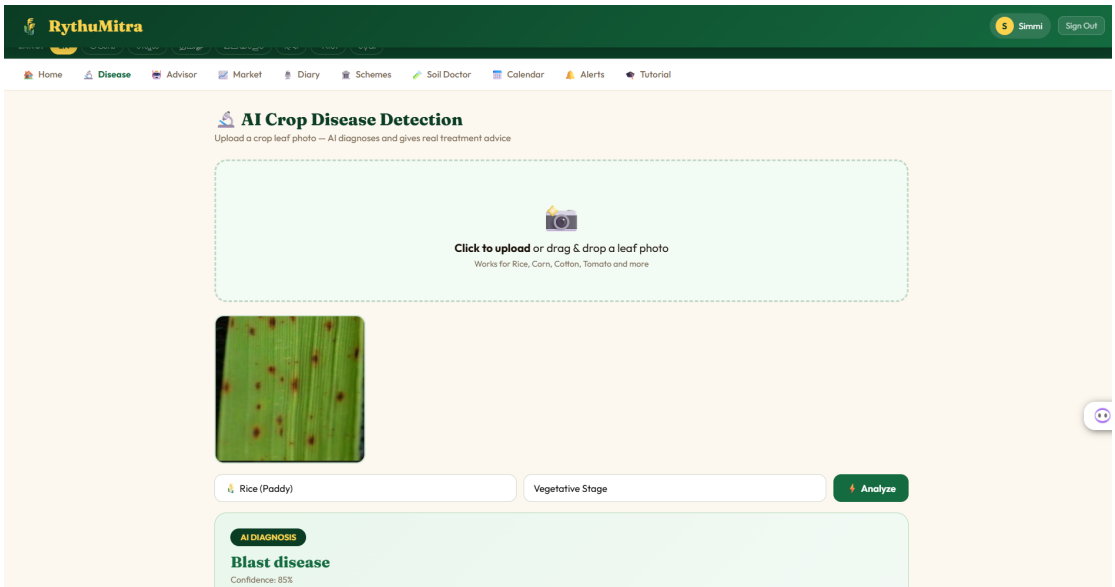

Fig. 6.1 Crop Detection

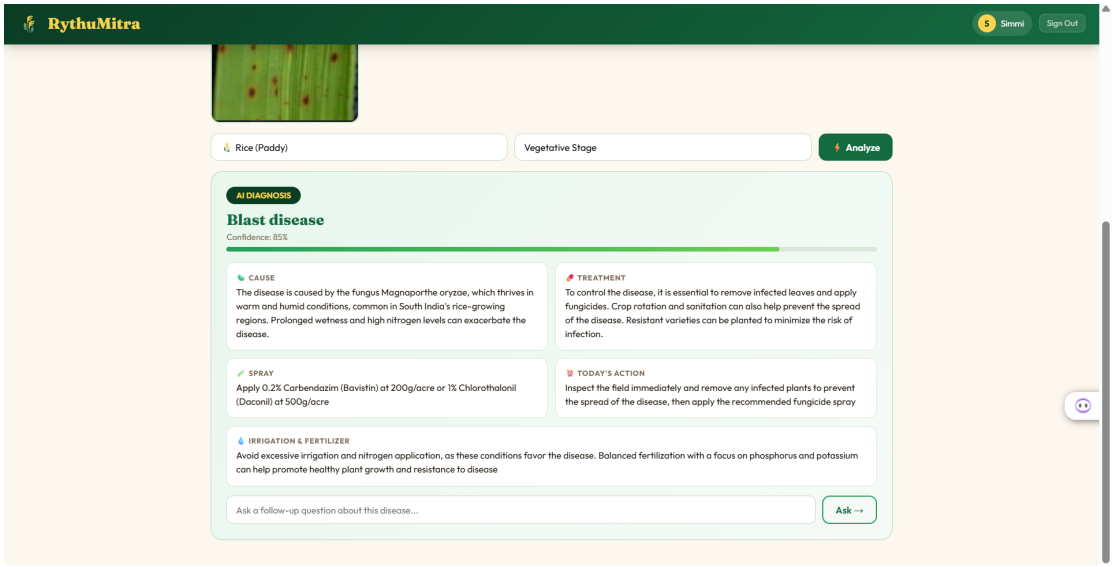

Fig. 6.2 Crop Detection

6.3.2 Sample Results

- Input: Leaf image of rice crop
- Output: Detected disease (e.g., Brown Spot)
- Confidence: High probability score
- Recommendation: Suggested fertilizer and treatment methods

The results demonstrate that the AI model can assist farmers in early disease detection and preventive action.

Table 6.2 Model Accuracy Results

Crop	Accuracy (%)
Rice	91
Corn	93
Cotton	90

6.4 Recommendation System Results

The recommendation module provided actionable suggestions based on the predicted disease. These recommendations included fertilizer usage, pest control methods, and irrigation practices.

The system ensured that the recommendations were relevant to the detected disease and easy to understand. This feature enhances the practical usability of the system by guiding farmers toward corrective measures.

Table 6.3 Disease Recommendation Mapping

Disease	Recommendation
Leaf Smut	Apply Potassium fertilizer + fungicide
Brown Spot	Use balanced NPK fertilizer and Zinc
Bacterial Blight	Apply copper-based bactericide
Common Rust	Spray Mancozeb fungicide
Gray Leaf Spot	Nitrogen management + fungicide
Blight	Apply Carbendazim

6.5 Blockchain Module Results

The blockchain-based scheme application module was tested to evaluate its functionality and reliability. The system successfully enabled users to upload documents, which were stored securely using IPFS.

Each application was recorded on the blockchain through smart contracts. A unique transaction hash was generated for each submission, ensuring transparency and traceability.

6.5.1 Observations

- All transactions were recorded successfully on the blockchain.
- Document hashes stored on the blockchain ensured data integrity.
- The system prevented unauthorized modification of records.

These results confirm that blockchain technology provides a secure and tamper-proof mechanism for managing agricultural scheme applications.

6.6 IPFS Storage Results

The IPFS-based storage system was used to store user-uploaded documents. Each file was assigned a unique hash, which was used for retrieval.

The system demonstrated reliable storage and retrieval of documents without dependency on centralized servers. This improves data security and availability.

6.7 Market and Weather Advisory Results

The advisory module was tested for real-time data integration. The system successfully fetched and displayed market prices and weather conditions.

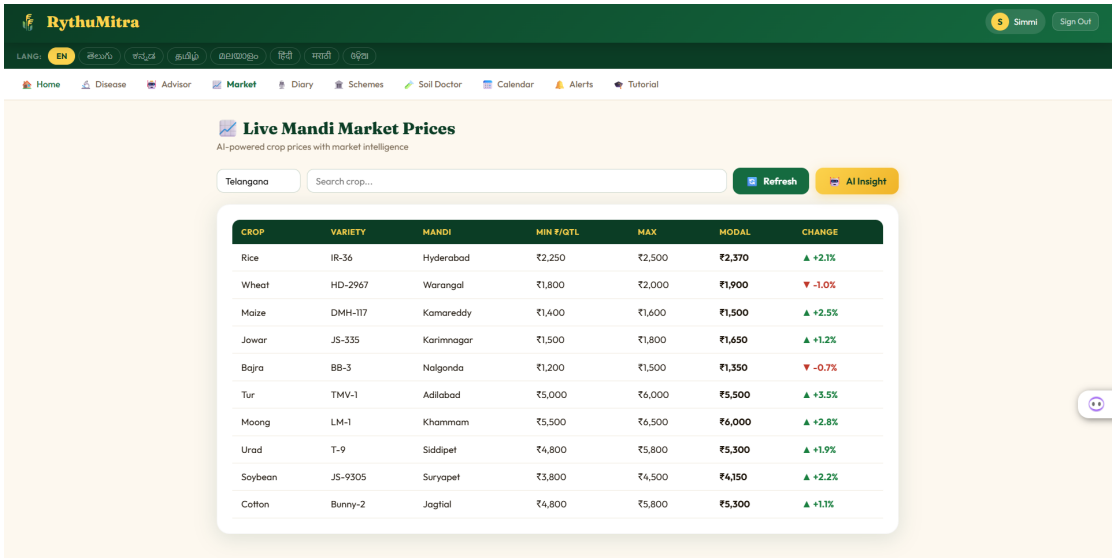

Fig. 6.3 Market Prices

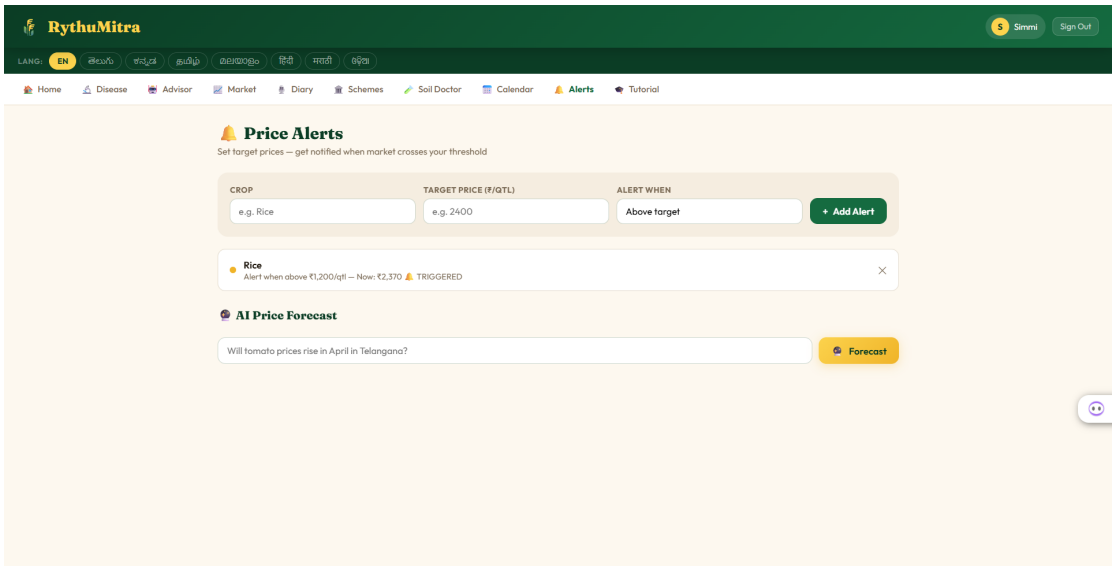

Fig. 6.4 Price Alerts

6.7.1 Key Observations

- Real-time data was retrieved efficiently from external APIs.
- Information was displayed clearly on the dashboard.
- Users could access relevant data for decision-making.

This module enhances the system by providing timely and useful agricultural insights.

6.8 User Interface Evaluation

The user interface was evaluated based on usability, accessibility, and responsiveness. The dashboard was designed to be simple and intuitive, allowing users to navigate easily between modules.

6.8.1 Usability Features

- Easy image upload functionality
- Clear display of results and recommendations
- Simple navigation between modules
- Support for multilingual interaction

The interface is suitable for users with limited technical knowledge, improving overall adoption.

6.9 Voice Interaction Results

The voice interaction module was tested to evaluate its usability and responsiveness. The system successfully converted user speech into text using Speech-to-Text (STT) techniques and processed user commands efficiently.

The module was able to handle basic user queries such as requesting crop information, navigating the system, and recording entries in the farm diary.

Additionally, the system demonstrated the capability to generate responses that can be presented in both text and audio formats using Text-to-Speech (TTS).

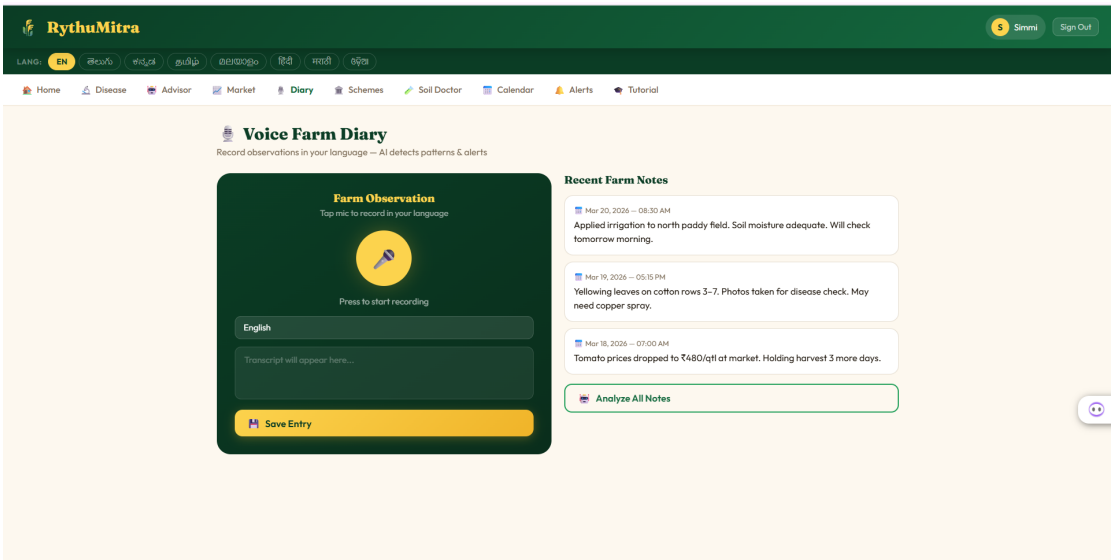

Fig. 6.5 Voice Driven Farm Diary

6.9.1 Observations

- Voice input was accurately converted into text in most cases.
- The system responded quickly to user commands.
- The feature improved accessibility for users with limited literacy.
- The module provided a user-friendly and interactive experience.

6.10 Performance Analysis

The overall system performance was analyzed based on multiple parameters:

6.10.1 Accuracy

The AI model achieved satisfactory accuracy in disease detection, demonstrating its capability to classify crop diseases effectively.

6.10.2 Response Time

The system provided quick responses for image processing and data retrieval. The response time was acceptable for real-time applications.

6.10.3 Scalability

The modular architecture allows the system to scale efficiently with increasing users and data.

6.10.4 Security

The use of blockchain and IPFS ensures secure data handling and prevents unauthorized access or modification.

6.11 Comparative Discussion

Compared to existing systems, the proposed RythuMitra platform provides a more comprehensive solution by integrating multiple functionalities into a single system.

- Existing systems focus only on disease detection or advisory services.
- The proposed system combines AI, Blockchain, and real-time data.
- Provides both analytical and transactional capabilities.

This integration improves usability and efficiency for farmers.

6.12 Limitations

Despite its advantages, the system has certain limitations:

- Accuracy depends on the quality of input images.
- Limited dataset for some crop categories.
- Requires internet connectivity for real-time features.
- Blockchain transactions may introduce slight delays.

6.13 Future Improvements

The system can be further enhanced by:

- Expanding the dataset to include more crops and diseases
- Improving model accuracy using advanced architectures
- Adding offline support for rural areas
- Enhancing voice-based interaction capabilities

6.14 Conclusion

The results demonstrate that the RythuMitra system successfully integrates multiple technologies to provide a comprehensive agricultural solution. The system improves disease detection, enhances transparency in scheme applications, and provides real-time advisory services.

Overall, the system contributes to smart and sustainable agriculture by empowering farmers with accessible and intelligent tools.

CHAPTER 7

CONCLUSION AND FUTURE SCOPE

7.1 Conclusion

The proposed system, *RythuMitra – A Multilingual Voice-First AI Farming Companion*, successfully demonstrates the integration of modern technologies such as Artificial Intelligence, Blockchain, and Web-based systems to address key challenges in agriculture. The system provides a unified platform that assists farmers in crop disease detection, decision-making, and secure access to government schemes.

The AI-based crop disease detection module, implemented using Convolutional Neural Networks (CNNs), effectively identifies diseases in crops such as rice, corn, and cotton. The system generates accurate predictions along with relevant recommendations, enabling farmers to take timely corrective actions and improve crop productivity.

The integration of blockchain technology ensures transparency and security in government scheme applications. By utilizing smart contracts and IPFS for decentralized storage, the system eliminates the risks associated with data tampering and manual processing, thereby increasing trust and efficiency.

In addition, the system incorporates real-time advisory services such as market price updates and weather information, helping farmers make informed decisions regarding crop management and sales. The inclusion of a multilingual voice-based interface further enhances accessibility, especially for users with limited literacy and technical knowledge.

Overall, the RythuMitra system provides a comprehensive and practical solution for modern agriculture by combining multiple functionalities into a single platform. The system contributes to improving productivity, transparency, and accessibility, thereby supporting the vision of smart and sustainable agriculture.

7.2 Future Scope

Although the proposed system achieves its intended objectives, there are several opportunities for further enhancement and expansion.

- **Expansion to More Crops:** The system can be extended to support a wider variety of crops and diseases by incorporating larger and more diverse datasets.
- **Improved Model Accuracy:** Advanced deep learning architectures such as EfficientNet or Vision Transformers can be used to improve prediction accuracy and robustness under real-world conditions.
- **Mobile Application Development:** A dedicated mobile application can be developed to increase accessibility for farmers in rural areas and provide offline capabilities.
- **Multilingual Enhancement:** The voice-based interface can be expanded to support more regional languages, improving usability across different regions.
- **Real-Time Monitoring using IoT:** Integration with IoT sensors can enable real-time monitoring of soil conditions, temperature, and humidity for better crop management.
- **Advanced Blockchain Integration:** The blockchain module can be enhanced to include automated eligibility verification and direct benefit transfer mechanisms.
- **Offline Functionality:** Developing offline capabilities for core features can make the system more accessible in areas with limited internet connectivity.
- **Predictive Analytics:** The system can be extended to include predictive analytics for yield prediction and crop planning.
